

Q- Create a one-page infographic that outlines the SDLC phases (Requirements, Design, Implementation, Testing, Deployment) and highlight the importance of each phase and how they interconnect.

1. Requirement Gathering

- Understand client needs clearly to define the system's overall purpose.
- Identify required features and user expectations for accurate project planning.
- **Importance:** Clear requirements prevent confusion and guide the entire development process effectively.

2. Design

- Create system architecture showing structure, components, and data flow connections.
- Prepare UI layout and database design for smooth development execution.
- **Importance:** Good design works as a blueprint, reducing errors during coding.

3. Implementation (Development)

- Developers write code based on approved design documents and standards.
- Build individual modules and integrate them to form complete software.
- **Importance:** Converts planned designs into a functioning and usable software system.

4. Testing

- Check software for bugs, performance issues, and missing functionality.
- Validate requirements and ensure the system behaves correctly under conditions.
- **Importance:** Ensures product quality, reliability, and safety before final deployment.

5. Deployment

- Release the tested software into the client's real working environment.
- Users access system features and begin using the application daily.
- **Importance:** Deployment delivers real business value by making the software operational.

6. Maintenance

- Fix issues reported by users after the system becomes live.
- Add updates, new features, and improve overall system performance.
- **Importance:** Keeps software secure, stable, and updated over long-term usage.
